EXECUTIVE SUMMARY

The Southern California Association of Governments (SCAG) developed the 2016 Regional Transportation Plan/Sustainable Communities Strategy (2016 RTP/SCS) for the SCAG region with a calendar year 2040 planning horizon. The RTP/SCS is a long-range plan that serves as a blueprint to help strategize for and achieve a coordinated regional transportation system. The SCAG region includes the counties of Imperial, Los Angeles, Orange, Riverside, San Bernardino, and Ventura. The RTP is used to guide the development of the Federal Transportation Improvement Programs as well as other transportation programming documents and plans. The RTP outlines the region's goals and policies for meeting current and future mobility needs, providing a foundation for transportation decisions by local, regional and state officials that are ultimately aimed at achieving a coordinated and balanced transportation system. Pursuant to Senate Bill (SB) 32 (2008), the SCS is developed as part of the RTP and outlines land use growth strategies that provide for more integrated land use and transportation planning, and maximize transportation investments. As such, like the 2012 RTP/SCS, the 2016 RTP/SCS contains regional transportation investments and integrated land use strategies over a 20-year period. Built upon the progress made since the 2012 RTP/SCS while recognizing the current conditions of land use and transportation throughout the region, the 2016 RTP/SCS is prepared to respond to a changing region by meeting the challenges and creating conditions and infrastructure that motivate increased mobility and accessibility; expanded transportation options; broader economic growth; equitably distributed benefits; and sustainability.

In support of the 2016 RTP/SCS, a Program Environmental Impact Report (PEIR) is being prepared. As part of the PEIR, this health risk assessment (HRA) was prepared to assess the potential carcinogenic health risks from emissions of diesel particulate matter (DPM) and other air toxics from motor vehicles on major freeways and transportation corridors. The HRA quantitatively analyzes only the potential carcinogenic impacts from motor vehicles traveling on major freeways. Non-cancer health risk were not addressed because the risks from air toxics emitted by motor vehicles are dominated by potential cancer risk, and non-cancer health risks from motor vehicles have been shown in other studies to not be of concern. Only motor vehicle emissions on freeways were quantitatively evaluated because emissions from other transportation modes and on other transportation corridors are much less than emissions on major freeways. Thus, this HRA yields a reasonable worst-case impact analysis.

The HRA evaluates 16 freeway segments, including eight freeway segments that were evaluated in the 2012-2035 RTP/SCS PEIR and eight additional segments selected for evaluation. The overview of freeway segments that were evaluated is shown in Figure ES-1 (*Overview Freeway*

Segments to be Evaluated). Emissions of DPM from each segment were calculated using the SCAG Transportation Demand Model VMT data for 2012 base year and projections for 2040. SCAG VMT data are provided for heavy duty vehicles and light/medium duty vehicles. The 2012 base year transportation network included the most recently adopted 2015 Federal Transportation Improvement Plan (FTIP) projects, which was adopted in September 2014 and obtained a federal approval in December 2014. So, the 2012 base year transportation network does capture the recent progress on the transportation projects side per the 2015 FTIP. The most current version of the California Air Resources Board (CARB) mobile source emissions model (EMFAC2014) was used to obtain emission factors of particulate matter less than 10 microns diameter in diesel-fueled vehicles, which were assumed equal to DPM emission factors.

The potential impacts of emissions from a representative 1-mile long portion of the freeway segment were evaluated with the CARB-approved AERMOD dispersion model (Version 15181) and meteorological data obtained from South Coast, Imperial, and Ventura Air Districts' monitoring sites. The calculated DPM concentration was then used to calculate the potential carcinogenic risk using the most current HRA guidelines published by the California Office of Environmental Health Hazard Assessment¹ (2015). The potential cancer risk calculated for DPM was increased by 5 percent to account for the additional organic gases of acetaldehyde, benzene, 1,3-butadiene, and formaldehyde based on observations of past data.

The potential cancer risk for residences was evaluated for a 30-year exposure, 9-year exposure and 70-year exposure. The potential cancer risk at worker receptors and sensitive receptors was also calculated. The sensitive receptors evaluated include senior centers, day care centers and schools, but the risk at those receptors was less than the maximum residential risk due to two primary reasons: (1) the duration of exposure at sensitive receptors is much less than assumed for residential exposure and (2) many of the sensitive receptors are further away from the freeway than the residential receptors (see Appendix C).

The 30-year maximum exposed individual residential (MEIR) cancer risk for each transportation segment evaluated for each of the Simulations 2 through 5, is reduced from the baseline conditions represented by Simulation 1 (Existing Conditions) as shown in Table ES-1 (*Summary Maximum Exposed Individual Residential 30-year Exposure Cancer Risk [cancer risk per million exposed persons]*). The MEIR cancer risk is on the order of 50 to 90 percent less than baseline conditions. This is due to the dramatic reduction in emissions that are expected due to the federal and state regulations that require reduced emissions from on-road heavy-duty diesel trucks

¹ California Office of Environmental Health Hazard Assessment

(HDDT). By 2040, emissions per mile from HDDT will be on the order of only 5 percent of the emissions per mile in 2015. Three simulations (Simulation 3, Simulation 4, and Simulation 5) have comparable reductions in exposure to cancer risk, with Simulation 5 (the Intensified Land Use Alternative) achieving the greatest reduction. This is because there is very little difference in HDDT vehicle miles traveled on the transportation segments in 2040 under any of the simulations (differences in HDDT mileage range from less than 1 to about 5 percent among the simulations). The MEIR cancer risk for Simulations 2 through 5 ranges from 93 in a million to 9 in a million cancer risk for 30-year exposure, 66 in a million to 6 in a million cancer risk for 9-year exposure, and 106 in a million to 10 in a million cancer risk for 70-year exposure. The exposed worker risk for Simulations 2 through 5 ranges from 7 in a million to 1 in a million cancer risk. The 70-year MEIR cancer risk for the No Project Alternative from the eight original freeway segments has decreased from the 2012-2035 RTP/SCS PEIR for the following reasons: 1) the emission factors for HDDT projected by the current version of the EMFAC model for 2040 are much less (on the order of 95 percent less) than the emission factors used in the 2012-2035 RTP/SCS PEIR for 2035; and 2) the vehicle mileage projected by the current SCAG transportation demand model is different than what was projected in the 2012-2035 RTP/SCS PEIR because a more updated 2012 Base Year transportation network is being used for this 2016 RTP/SCS. The combined result of these differences show a decrease in the overall risk to residential, worker and sensitive receptors in the current predictions when compared with the previous analyses.

1 INTRODUCTION

The Southern California Association of Governments (SCAG) 2016-2040 Regional Transportation Plan/Sustainable Communities Strategy (2016 RTP/SCS, “Plan” or “Project”) is a long-range transportation plan that provides a vision for regional transportation investments that are integrated with land use strategies for a more than 20-year period. SCAG serves as a Metropolitan Planning Organization (MPO), a Council of Governments (COG) and a Multi-County Designated Transportation Planning Agency representing the approximately 18.7 million residents living within approximately 38,000 square miles represented by multiple jurisdictions: six-County area comprised of Imperial, Los Angeles, Orange, Riverside, San Bernardino, and Ventura Counties and 191 cities, 16 Federally recognized Tribal Sovereign Nations; and 15 Subregional entities that have been recognized by the Regional Council, SCAG’s governing body, as partners in the regional policy planning process.

SCAG is the lead agency under the California Environmental Quality Act (CEQA) with the responsibility for consideration of the 2016 RTP/SCS for approval. As the lead agency, SCAG has determined to prepare a Program Environmental Impact Report (PEIR) for the 2016 RTP/SCS.

The PEIR is a programmatic document that provides a region-wide assessment of the potential significant environmental effects of the 2016 RTP/SCS. The PEIR provides a regional consideration of direct and indirect effects, growth-inducing impacts, and cumulative effects of the 2016 RTP/SCS at a programmatic level. The PEIR includes a range of reasonable alternatives to the 2016 RTP/SCS, including the No Project alternative and alternatives that are capable of achieving most of the basic objectives of the 2016 RTP/SCS and that may be capable of avoiding or substantially lessening any of the significant environmental effects of the 2016 RTP/SCS. The PEIR includes performance standard-based mitigation measures that are capable of avoiding and reducing the significant effects of the 2016 RTP/SCS to the maximum extent practicable.

In support of the 2016 RTP/SCS, a PEIR is being prepared. As part of the PEIR, this HRA was prepared to assess the potential cancer risks from emissions of diesel particulate matter (DPM) and other air toxics from motor vehicles on major freeways and transportation corridors. Major freeways have the highest potential for DPM risk due to the density of HDT traffic, emission rates from HDT traffic, and proximity/number of residential and sensitive receptors near freeways. The HRA quantitatively analyzes only the potential carcinogenic impacts from motor vehicles traveling on major freeways. Non-cancer health risks were not addressed because the risks from air toxics

emitted by motor vehicles are dominated by potential cancer risk and non-cancer health risks from motor vehicles have been shown in other studies to not be of concern.

2 HEALTH RISK ASSESSMENT METHODOLOGY

The diesel-exhaust health risk assessment was conducted in seven steps:

- 1) Determine which land use development pattern and transportation investment scenarios will be evaluated in the health risk assessment simulations;
- 2) Identify major freeway and transportation corridors of interest within the simulations;
- 3) Select representative transportation segments from the major freeways or transportation corridors that will be used in the detailed analysis to yield a reasonable worst-case assessment of the potential cancer risk associated with the simulations under evaluation;
- 4) For each of the simulations, determine emissions of diesel exhaust from all of the selected representative transportation segments;
- 5) Determine receptors of interest (including hypothetical worst-case receptors) near the selected representative transportation segments at which the potential impact of diesel exhaust will be evaluated;
- 6) Model atmospheric dispersion of the emissions in order to determine the potential impact from emissions at receptors of interest and hypothetical receptors; and
- 7) Evaluate the potential cancer risk at the receptors of interest and hypothetical receptors.

2.1 SCENARIOS TO BE EVALUATED

The scenarios to be evaluated in this HRA were based on those recommended pursuant to the State California Environmental Quality Act (CEQA) Guidelines (California Code of Regulations, Chapter 3. Guidelines for the Implementation of CEQA). The PEIR includes evaluation of the proposed Project (2016 RTP/SCS) and three alternatives. This HRA includes these four scenarios in addition to the existing conditions scenario (baseline scenario), thereby resulting in five HRA simulations:

- Simulation 1: Represents Existing Conditions (or baseline simulation);
- Simulation 2: Represents future (2040) conditions under the No Project Alternative;
- Simulation 3: Represents future (2040) conditions under the 2016 RTP/SCS or the Proposed Project;
- Simulation 4: Represents future (2040) conditions under the 2012 RTP/SCS with Local Input Alternative;

- Simulation 5: Represents future (2040) conditions under the Intensified Land Use Alternative.

2.2 SELECTION OF REPRESENTATIVE TRANSPORTATION SEGMENTS

The SCAG regional transportation system includes approximately 70,904 existing lane miles². Clearly, one cannot assess potential health risks at all of those locations. Thus, a reasonable worst-case representative subset of highways and arterials was selected for analysis. The analysis focused on major freeways and transportation corridors. Passenger rail impacts were not quantitatively assessed because emissions from passenger rail are much less than emissions from major freeways and transportation corridors. For this analysis, 16 representative transportation segments were chosen from major freeway and transportation corridors in the six-county SCAG Region to yield a reasonable worst-case assessment of the potential impact of the five Evaluation Simulations throughout the SCAG Region. The logic for selection of the 16 representative transportation segments is as follows:

- Evaluate the eight transportation segments as used in SCAG's 2012-2035 RTP/SCS PEIR³ for comparison purposes.
- Select an additional eight transportation segments from major freeways and transportation corridors based on 2012 base year⁴ vehicle miles traveled (VMT) data and sensitive receptor locations. Qualifying freeway segments identified as having at least one sensitive receptor within 500 meters were then ranked based on heavy duty (HD) vehicles (primarily trucks) VMT, considering the amount of truck traffic in both directions. Segments were not considered that were considered distant from populated areas with minimal (i.e., less than two) sensitive receptors (e.g., near the base of the Grapevine on I-5) or where the additional segment was an extension of the one of the original 8 segments. In these cases, the next most appropriate segment was chosen following the criteria above.

Selection of the additional eight transportation segments involved consideration of a combination of quantitative and qualitative information. First, VMT data from 2012 base year transportation network, representing the most updated transportation network at the time of the preparation for

² SCAG Transportation Modeling, October 2015.

³ Program Environmental Impact Report, Southern California Association of Governments 2012-2035 Regional Transportation Plan/Sustainable Communities Strategy, December 2011, State Clearinghouse # 2011051018. Notice of Determination published April 9, 2012.

⁴ The 2012 base year transportation network that is being used for the 2016 RTP/SCS includes the most updated 2015 Federal Transportation Improvement Program (FTIP) projects as well as the projects included in the 2012 RTP/SCS as last amended in September 2014.

the 2016 RTP/SCS, were obtained from SCAG. These data provide 2012 base year VMT for both HD (both diesel and other fuel) and light/medium duty (LM, both diesel and other fuel) vehicles for all of the major freeways and transportation corridors in the SCAG Region. The VMT data are reported by SCAG from the Transportation Demand Model by geographic locations called links. For the purposes of this HRA, a freeway segment may consist of one or more links as defined later in this section. The lengths of the links vary, but are generally on the order of a mile long. The links were then ranked from highest to lowest average daily HD VMT. Average daily VMT was used instead of AM or PM peak VMT because the potential health risks from diesel exhaust are based on long-term (annual average) exposures for many years. The ranking was based on HD VMT rather than LM alone or HD plus LM VMT because nearly all of the HD vehicles are on-road heavy-duty diesel trucks (HDDT), while most of the LM vehicles are not diesel-fueled. Thus, HD VMT yields the highest potential diesel emissions.

The ranking was based on 2012 base year VMT data because those data were the most recent available at the time of the ranking. The 2012 base year VMT data incorporated the most recent 2015 Federal Transportation Improvement Program (FTIP) projects and the 2012 RTP/SCS projects as amended in September 2014. The 2015 FTIP was adopted in September 2014 and obtained federal approval in December 2014. Since the 2012 base year VMT data includes the 2015 FTIP projects and the 2012 RTP/SCS projects as last amended in September 2014, it is not expected that 2015 VMT data (even if it were available) would change the ranking obtained with the 2012 base year VMT data. Hence, the 2012 base year VMT data used in this HRA represented the most updated transportation network information existing at the time that the Notice of Preparation for this PEIR was issued (March 2015).

Second, the locations of sensitive receptors in the region were obtained from TomTom and TeleAtlas databases. The sensitive receptor locations were then plotted and the HD VMT data evaluated to select links that had the greatest combination of the density of nearby (within 500 meters) sensitive receptors and maximum HD VMT. A distance of 500 meters from the freeway links was used to capture the nearest and most dense areas of sensitive receptors and because previous studies by CARB have demonstrated that the potential health risk decreases dramatically with distance and the maximum impact is within 500 meters. Links that were geographically adjacent were connected as necessary to create a segment of length of from 2 to 6 miles such that a meaningful number of nearby sensitive receptors and nearby residents were present for that segment. Then one of the maximum HD VMT segments in each county was selected considering not only the quantitative information (HD VMT and numbers of sensitive receptors) but also the qualitative information such as evaluation of aerial photos showing

residential and commercial building density. After one worst-case segment was chosen in each of the six SCAG Region counties, additional two segments that had relatively high HD VMT were added (one in Los Angeles County and one in Riverside County).

The magnitude of the length of a segment to be evaluated is not critical because the maximum impact of diesel exhaust emissions occurs very near (less than 500 meters) and perpendicular to the segment. As long as the length of the segment is relatively longer than the distance to the impacted receptor, the potential impact at a receptor will be the same regardless of the length of the segment. A segment at least 1500 meters long (approximately 1 mile) is long enough to represent the impact at a receptor 500 meters away. Note that most of the maximally-affected residences, worker, and sensitive receptors are located less than 500 meters away.

It is recognized that VMT is a function not only of the number of vehicles but also the distance traveled by a vehicle. Therefore, if the number of vehicles is constant, a longer link will have a greater VMT than a shorter link. However, most of the links are of a similar length (on the order of 1 mile), and thus comparing VMT for a link is approximately the same as comparing vehicle counts. VMT is the parameter needed to perform emission and health risk assessment modeling, and thus VMT was used to rank the links. A brief analysis was conducted to confirm that ranking a segment by VMT versus vehicle counts does not change selection of the worst-case segment.

It is also recognized that total emissions for a segment are a function of VMT because, as discussed in Section 2.3, the emissions model yields emission factors in terms of grams per mile. Therefore, a longer segment will have greater emissions (grams per day) than a shorter segment, even if the vehicle counts are the same (because the longer segment will have greater VMT). However, the emissions for the longer segment are “spread out” over a longer distance, so the potential impact is the same. Thus, the ultimate length of a segment is not critical provided that it is long enough to adequately represent maximum impact at a meaningful number of sensitive receptors.

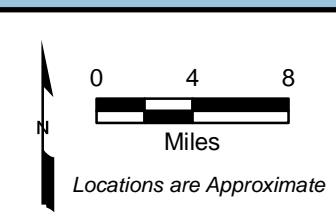

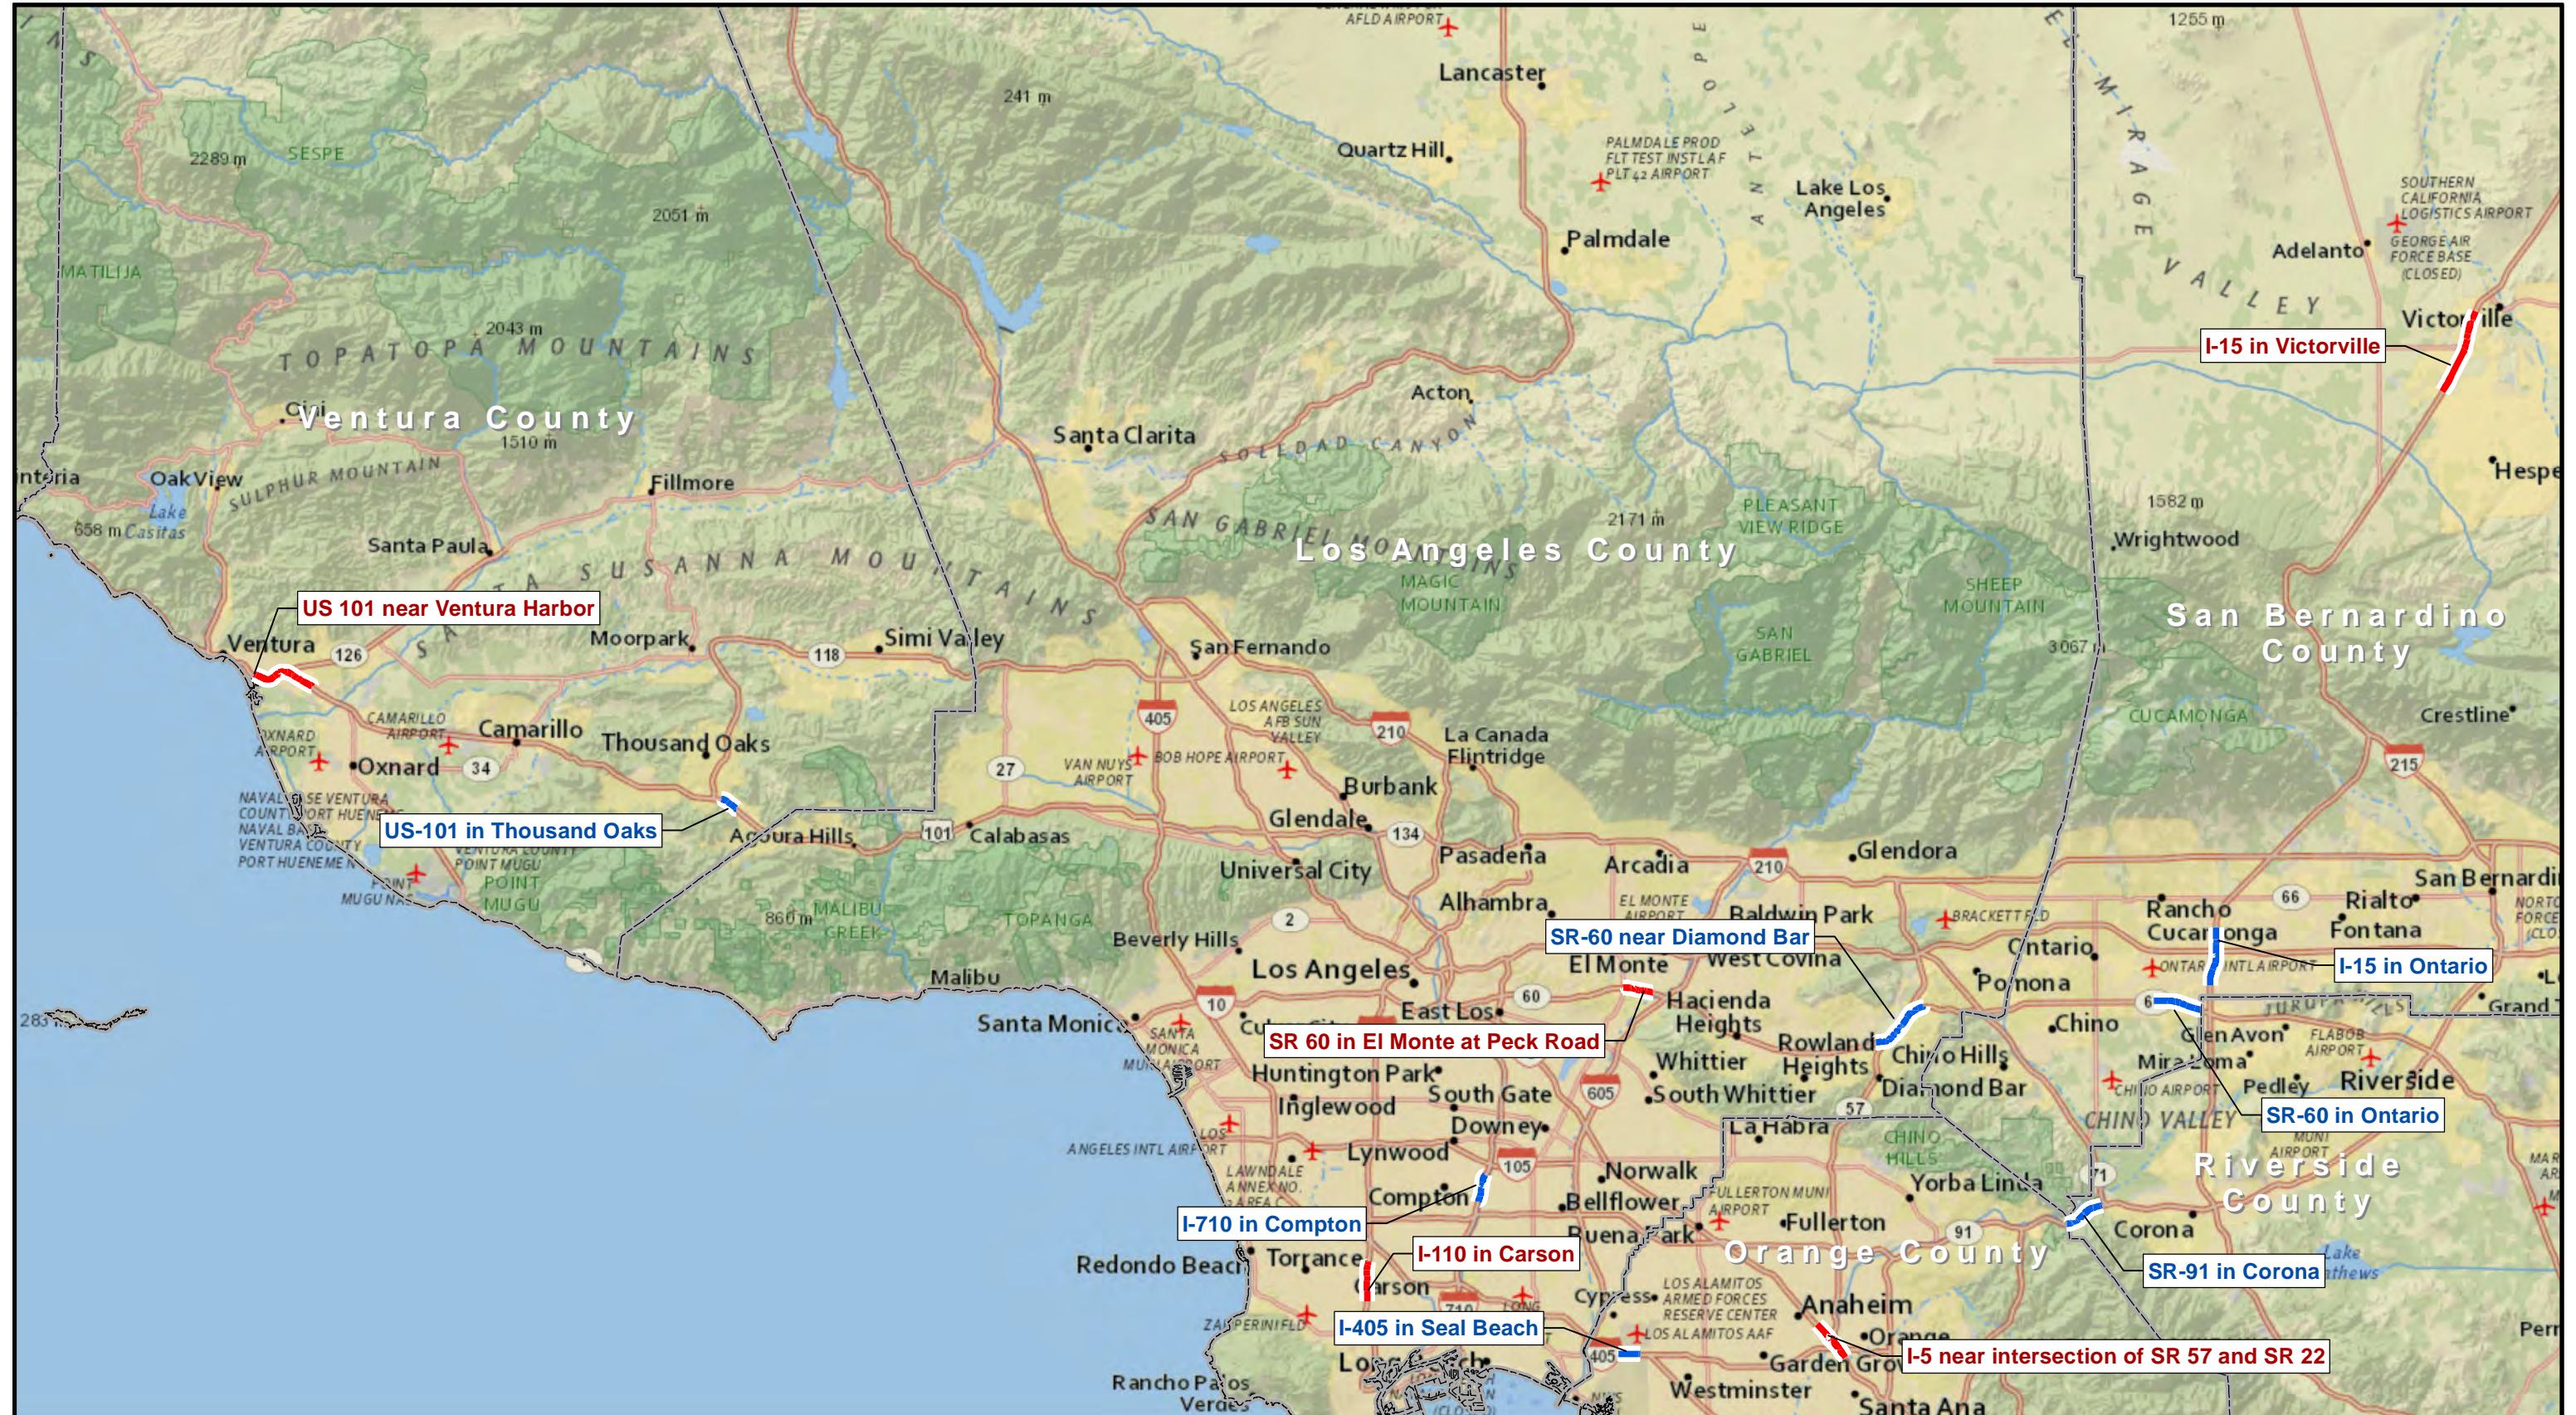

Initially, it was expected that major freeways would have greater HD VMT than major transportation corridors (e.g., bus and light rail), and it was expected that there would be sufficient nearby sensitive receptors to the major freeways such that the major freeways would represent worst-case conditions. This logic was confirmed by evaluating HD VMT for major transportation corridors in the SCAG Region compared to the freeways, and it was found that the HD VMT on the major freeway segments was much greater than for the transportation corridors. It was also found that there were numerous residential, worker, and sensitive receptors nearby the major freeways. Likewise, public transit corridors and airport diesel exhaust emissions are much less

than for the major freeways. Therefore, use of the major freeways for segment selection does represent a reasonable worst-case health impact analysis.

The HRA evaluated a total of 16 segments, including the eight segments evaluated in the 2012 RTP/SCS PEIR and eight additional segments selected for evaluation. These segments are shown in ES-1 (*Overview Freeway Segments to be Evaluated*) and Figures 2-1 through 2-3 (*Detailed Overview of SCAG Regions*), and individual details are located in Appendix A:

1. IMP I-8: Interstate 8 just east of El Centro (Imperial County); a 2012-2035 PEIR Segment. (Figure A-1, *IMP I-8 Segment Detail Map*)
2. IMP SR-78: State Road 78 Freeway in Westmorland (Imperial County); an additional segment. (Figure A-2, *IMP SR-78 Segment Detail Map*)
3. LA I-110: Interstate 110 in Carson (Los Angeles County); an additional segment. (Figure A-3, *LA I-110 Segment Detail Map*)
4. LA I-710: Interstate 710 in Compton, north of the intersection with SR 91 (Los Angeles County); a 2012-2035 PEIR Segment. (Figure A-4, *LA I-710 Segment Detail Map*)
5. LA SR-60 DB: State Road 60 Freeway near Diamond Bar (Los Angeles County); a 2012-2035 PEIR Segment. (Figure A-5, *LA SR-60 DB Segment Detail Map*)
6. LA SR-60 SEM: State Road 60 Freeway near South El Monte at Peck Rd (Los Angeles); an additional segment. (Figure A-6, *LA SR-60 SEM Segment Detail Map*)
7. ORA I-5: Interstate 5 in Orange near intersection of SR 57 and SR 22 (Orange County); an additional segment. (Figure A-7, *ORA I-5 Segment Detail Map*)
8. ORA I-405: Interstate 405 in Seal Beach, east of the I-605 interchange (Orange County); a 2012-2035 PEIR Segment. (Figure A-8, *ORA I-405 Segment Detail Map*)
9. RIV I-10: Interstate 10 in the Banning area (Riverside County); an additional segment. (Figure A-9, *RIV I-10 Segment Detail Map*)
10. RIV I-15: Interstate 15 near Temecula (Riverside County); an additional segment. (Figure A-10, *RIV I-15 Segment Detail Map*)
11. RIV SR-91: State Road 91 Freeway in Corona, east of the intersection with SR 71 (Riverside County); a 2012-2035 PEIR Segment. (Figure A-11, *SR-91 Segment Detail Map*)
12. SB I-15 ONT: in Ontario (San Bernardino County); a 2012-2035 PEIR Segment. (Figure A-12, *SB I-15 ONT Segment Detail Map*)

13. SB I-15 VIC: Interstate 15 in the Victorville area (San Bernardino County); an additional segment. (Figure A-13, *SB I-15 VIC Segment Detail Map*)
14. SB SR-60: State Road 60 Freeway in Ontario, west of the I-15 interchange (San Bernardino County); a 2012-2035 PEIR Segment. (Figure A-14, *SB SR-60 Segment Detail Map*)

2.3 POTENTIAL EMISSIONS FROM EACH TRANSPORTATION SEGMENT

Emissions were estimated for each transportation segment and Evaluation Simulations with the latest EMFAC2014 California mobile source emissions model. This emissions model is published by the California Air Resources Board (CARB) for use in California to estimate emissions from mobile sources. The EMFAC2014 model is currently being reviewed by USEPA. The model includes County-specific mobile source profiles, including fleet mix and other parameters that affect emissions. Therefore, EMFAC2014 was run to obtain emission factors (grams per mile) for each of the six counties and for calendar years 2015 and 2040 to account for the Evaluation Simulations and transportation segment locations.

Calendar year 2015 was used to calculate the emission factors for Evaluation Simulation 1, Existing Conditions, as the Notice of Preparation was issued in spring of 2015. The 2015 emission factors were coupled with the 2012 VMT (which reflects the 2015 FTIP and is the best VMT data available for existing conditions) to obtain total emissions per segment. For Evaluation Simulations 2 through 5, calendar year 2040 emission factors were coupled with 2040 VMT estimates. The 2040 emission factors represent the best estimate by CARB as to the future fleet mix composition and emission parameters.

The EMFAC emissions model yields emissions of the criteria pollutants (e.g., nitrogen oxides, particulate matter, etc.), not air toxics (e.g., diesel exhaust, acetaldehyde, etc.). However, diesel exhaust consists of particulate matter of less than 10 micron mean aerodynamic diameter (PM_{10}), and PM_{10} is one of the criteria pollutants. PM_{10} from diesel-fueled vehicle exhaust was used to represent diesel exhaust emissions. EMFAC estimates PM_{10} emissions from other sources as well (e.g., brake/tire wear, gasoline vehicle exhaust, etc.), but those sources within EMFAC were not counted as diesel exhaust. EMFAC does not yield emissions of other air toxics associated with vehicle travel, specifically benzene, acetaldehyde, 1,3-butadiene, and formaldehyde. A methodology to account for the risk contribution of these additional air toxics was developed and is discussed in Section 2.6.

EMFAC provides emission factors individually for each vehicle class and model year, and EMFAC2014 can be run for 13 or 34 different vehicle classes (times 2 for diesel versus gasoline). For this analysis, 13 vehicle classes (times 2 for diesel versus gasoline) were used, as the SCAG VMT data are already lumped into only 2 groups (HD and LM), thus running 34 vehicle classes (times 2 for diesel versus gasoline) causes unnecessary complexity and does not improve accuracy. Furthermore, most of the potential health risk is from HDDT; thus no additional health risk information is gleaned by using 34 vehicle classes. For each county, the HD and LM VMT

was assigned proportionally to each of the vehicle classes and fuel types according to the county-specific fleet mix in EMFAC for calendar year 2015 or 2040. Fleet aggregate emission factors by vehicle class were used based on the county-specific fleet mix of model years for that vehicle class. The EMFAC fleet mix and proportional distribution of 2015 and 2040 VMT are shown in Appendix B by county and calendar year. Appendix B also shows the PM₁₀ emission factors from EMFAC2014 by vehicle class.

The PM₁₀ emission factors from EMFAC by vehicle class for diesel-fueled vehicles (grams per mile) were then multiplied by the average daily VMT for the transportation segment to obtain total emissions (grams per day) of DPM. The VMT data for Simulation 1, Existing Conditions, was prepared by using the 2012 base year, but includes projects in the 2015 FTIP adopted in September 2014, as well as projects in the 2012-2035 RTP/SCS as last amended in September 2014. The VMT data for Simulations 2 through 5 were prepared for calendar year 2040 and were developed with their travel demand modeling system. Table 2-1 (*Average Daily VMT for Selected Transportation Segments and Evaluation Simulations*) shows the average daily VMT by transportation segment, direction, and Evaluation Simulation. The VMT was then multiplied by the EMFAC2014 emission factors to yield the emissions (grams per day) shown in Tables 2-2 through 2-6 (*DPM Emission Estimates for Simulations 1 through 5*). Emissions for each direction of the transportation segment were estimated separately because VMT differs by direction. Additional calculation detail is presented in Appendix B.

The emissions calculated for calendar year 2040 are an over-estimate of what will actually occur, because EMFAC2014 only incorporates “on the books” regulations and emission reduction practices. Emissions from vehicles consistently decrease in the future as new technologies become available and new emission limits are required through regulations not yet enacted. Therefore, emissions in 2040 will be less than calculated herein even if the VMT forecasts are the same as currently estimated.

2.4 RECEPTORS OF INTEREST

Health risk is assessed at locations where persons can be exposed to the emissions. These locations are termed receptors. Receptors are classified according to what persons may be doing at the location. The receptor types are residential, work, or sensitive. Sensitive receptors include day care centers, schools, and senior centers. Residential and worker receptors within 1000 meters of each transportation segment, starting about 100 meters away from the outer edge of the freeway, were determined based on aerial photos of the transportation segment. The 1000 meter criterion was used to sufficiently capture where the health impacts may be expected to occur. Sensitive receptors were identified from the TomTom and TeleAtlas databases, and there are over 100 sensitive receptors in the vicinity of the 16 study segments. All of the receptors are shown on Figures C-1 through C-16 (*Modeled Receptors Segments 1 through 16*) in Appendix C. In areas where there were multiple residences and possible worker locations, receptors were placed in a grid pattern with 100-meter spacing out to 500 meters from the transportation segment and 250-meter spacing out to 1000 meters. The receptors were placed at UTM coordinates at even-100 meter locations (e.g., UTM 330100, 3782400) so that the model results could be input into the HARP 2 risk assessment model if needed (see Section 3.3). Actual physical mean sea level elevation of the receptors was used in the dispersion model, with the elevation data obtained from U.S. Geological Survey (USGS) Digital Elevation Model/Geographic Information System (DEM/GIS) data.

In addition to individual actual receptors, two additional sets of hypothetical receptors were evaluated. Risk calculations were conducted for the maximum impact point based on an assumption that any of the various receptor types (e.g., resident, worker, school, day care center, senior center) could be located at the maximum impact point using Segment 8, ORA I-405 (Interstate 405 in the Seal Beach area). A set of hypothetical receptors was used to show how the potential health risk decreases rapidly with distance away from the transportation segment using Segment 4, LA I-710 in the Compton area and Simulation 1 – Existing Conditions (see Section 3.4). The hypothetical receptor analysis also accounts for the possibility that in some cases there may be actual receptors closer to the freeway than 100 meters.

2.5 ATMOSPHERIC DISPERSION MODELING AND IMPACT ASSESSMENT

The CARB-approved AERMOD dispersion model (Version 15181, as provided by BEE-Line Software, Version 11.01) was used and run with regulatory defaults as required by the Air Districts. The three primary inputs to the AERMOD model are the emissions, receptors, and meteorological data. Worst-case meteorological data provided by the relevant Air Districts (South

Coast, Ventura, Imperial) were used as shown in Table 2-7 (*Meteorological Data Used for Dispersion Modeling*). The meteorological data are selected and provided by the Air Districts to be used in the AERMOD model for all dispersion modeling. The calendar years of meteorological data provided by the Air Districts is not intended to match the calendar years in which a source is or will be emitting, as the Districts select a worst-case set of data to be used for all modeling in the District. The nearest representative meteorological station to each of the transportation segments was used.

Table 2-7
Meteorological Data Used for Dispersion Modeling

16	VEN US-101 TO	Ventura / Thousand Oaks	Reseda	2008, 09, 10, 11, 12

The transportation segments were modeled as a series of volume sources for each direction of the freeway. The volume sources are square in plan view (i.e., looking from above) with the width equal to the physical transportation segment width for each direction plus 3 meters to account for initial mechanical turbulence. Adding 3 meters to the volume source is standard practice per Caltrans and CARB modeling guidance for roadway dispersion modeling. To be conservative,

only one 3-meter addition was made (i.e., to the outside of the roadway) because in many cases the inside edge of the volume sources are adjacent (i.e., there is no median, only a concrete barrier separating the different directions). The release height for the emissions was also conservatively chosen as 2 meters to represent the average height of HDDT and other diesel-fueled vehicle exhausts. No elevated transportation segments were modeled (i.e., no overpasses or elevated or depressed on or off-ramps). Actual physical mean sea level elevation of the transportation segment volume sources was used, obtained from USGS DEM/GIS data.

In order to reduce computation time, a one-mile portion of the transportation segment was modeled. The modeled mile was chosen to encompass the most sensitive receptors. As discussed previously, a one-mile modeled portion of the transportation segment will yield the same maximum impact concentrations as a longer portion.

For purposes of the dispersion model, unit emission rates (i.e., 1 gram per second [g/sec]) for each direction were entered into the model. Thus, the dispersion model yields “relative impact concentrations” in terms of concentration per unit emission rate (micrograms per cubic meter / gram per second, or ug/m³ / g/sec). The relative concentration (ug/m³ / g/sec) can then be multiplied by the emission rate (g/sec) for the transportation segment to obtain the impact concentration (ug/m³).

The maximum impact dispersion model results for each of the segments are shown in Appendix D and electronic copies of the model input.

2.6 HEALTH RISK ASSESSMENT

The DPM concentrations determined by the dispersion model at the receptors of interest were used to evaluate the potential carcinogenic risk of the five simulations. Cancer risk was used as a surrogate for all associated health risks since it is known that near major freeways and transportation corridors the greatest potential health effect is from DPM emissions and long term carcinogenesis (see Section 3.5).

As stated previously, only DPM emissions are estimated with the EMFAC emissions model, and there are an additional four major carcinogenic air toxics (i.e., acetaldehyde, benzene, 1,3-butadiene, and formaldehyde) that are emitted by vehicles. Other air toxics can be estimated using a US Environmental Protection Agency (USEPA) emissions model, MOVES2014. The MOVES2014 model replaces the previous USEPA emissions model for mobile sources called

MOBILE6.2a. The 2012-2035 PEIR⁵ demonstrated that 96.3 percent of the total cancer risk was due to DPM, with the additional four air toxics contributing only 3.7 percent. However, the 2012-2035 PEIR used the MOBILE6.2a emissions model. Therefore, an analysis was conducted to determine if the same ratio would result if the current MOVES2014 emissions model were used. The analysis showed that when the MOVES2014 emissions model is used, DPM was responsible for nearly 99 percent of the total risk from heavy duty diesel trucks and from 96.1 to 96.3 percent of the total risk for all vehicle classes⁶. Accordingly for purposes of the health risk assessment, the potential health risk calculated by using only DPM was conservatively increased by 5 percent to account for the additional air toxics of acetaldehyde, benzene, 1,3-butadiene, and formaldehyde (see Appendix E for further details).

2.6.1 Residential Cancer Risk

For a given ambient concentration of DPM, the potential cancer risk is a function of the types of persons exposed (adults, children, pregnant women, etc.) and the duration of exposure. The California Office of Environmental Health and Hazard Assessment (OEHHA) has published guidelines for calculating potential cancer risk. The most recent version of the guidelines, Air Toxic Hot Spots Program Guidance Manual for Preparation of Health Risk Assessments dated February 2015⁷ (Guidance), was used to calculate the DPM cancer risk for each of the segments using the Guidance (see Appendix D). Consistent with the Guidance, potential cancer risk is calculated by first determining the dose of DPM and then multiplying the dose times the exposure duration and cancer potency factor, as shown in the following equation:

⁵ *Program Environmental Impact Report*, op cit. Appendix F.

⁶ Letter from James Dill and Russell Erbes to Mr. Eric Charlton dated February 3, 2015. Available from Mr. Eric Charlton, Sapphos Environmental, Inc.

⁷ *Air Toxic Hot Spots Program Guidance Manual for Preparation of Health Risk Assessments*, February 2015. California Office of Environmental Health Hazard Assessment. Available at http://oehha.ca.gov/air/hot_spots/hotspots2015.html, last accessed September 2015.

Residential Dose (Guidance Equation 5.4.1):

$$\text{Dose-air} = C_{\text{air}} \times \{\text{BR/BW}\} \times A \times EF \times 10^{-6}$$

Where,

Dose-air = dose through inhalation, mg/kg/d (only the inhalation pathway is applicable to DPM)

C_{air} = annual average concentration of DPM at the receptor of interest, ug/m³

$\{\text{BR/BW}\}$ = Daily breathing rate normalized to body weight, L/kg body weight-day

A = Inhalation absorption factor, unitless, assumed equal to 1

EF = Exposure frequency, unitless, calculated from days exposure per 365 days

10^{-6} = conversion factor micrograms to milligrams and liters to cubic meters

The Guidance recommends that for residential exposure the EF is 350/365 and for $\{\text{BR/BW}\}$ that the 95th percentile daily breathing rates should be used (Guidance Table 5.6). The 95th percentile breathing rates are as follows:

Third Trimester = 361 L/kg-day

0 to <2 years = 1090 L/kg-day

2 to <9 years = 861 L/kg-day

2 to <16 years = 745 L/kg-day

16 to <30 years = 335 L/kg-day

16 to <70 years = 290 L/kg-d

Residential Cancer Risk (Guidance Equation 8.2.4A)

$$\text{RISK}_{\text{inh-res}} = \text{Dose-air} \times \text{CPF} \times \text{ASF} \times \text{ED/AT} \times \text{FAH}$$

Where,

CPF = cancer potency factor, which for DPM is 1.1 (mg/kg/day)⁻¹

ASF = Age sensitivity factor, unitless

ED = Exposure Duration, years, for the specified age group

AT = Averaging Time for lifetime cancer risk, which is 70 years

FAH = Fraction of Time at Home, unitless

The Guidance recommends the following Age Sensitivity Factors (Guidance Table 8.3):

3rd Trimester	10
0 to <2 years	10
2 to <9 years	3
9 to <16 years	3
16 to <30 years	1
30 to <70 years	1

The Guidance recommends the following Fraction of Time at Home when there is a school within the 1 in a million cancer risk isopleth of the source, which is nearly always the case for freeways (Guidance Table 8.4):

3rd Trimester	1.0
0 to <2 years	1.0
2 to <9 years	1.0
9 to <16 years	1.0
16 to <30 years	0.73
30 to <70 years	0.73

When one combines the equation for Dose-air and for RISK_{inh-res}, the 30-year residential cancer risk is calculated as follows:

Residential 30-Year Exposure DPM Cancer Risk =

$$\begin{aligned}
 & [(C_{air} \times 361 \times 350/365 \times 10^{-6} \times 1.1 \times 10) \times (0.25 \text{ yrs} / 70 \text{ yrs}) \times 1.0]_{\text{third trimester}} + \\
 & [(C_{air} \times 1090 \times 350/365 \times 10^{-6} \times 1.1 \times 10) \times (2 \text{ yrs} / 70 \text{ yrs}) \times 1.0]_{0 \text{ to } <2 \text{ yrs}} + \\
 & [(C_{air} \times 745 \times 350/365 \times 10^{-6} \times 1.1 \times 3) \times (14 \text{ yrs} / 70 \text{ yrs}) \times 1.0]_{2 \text{ to } <16 \text{ yrs}} + \\
 & [(C_{air} \times 335 \times 350/365 \times 10^{-6} \times 1.1 \times 1) \times (14 \text{ yrs} / 70 \text{ yrs}) \times 0.73]_{16 \text{ to } <30 \text{ yrs}}
 \end{aligned}$$

The Guidance recommends that cancer risk be reported assuming 30-year exposure for residential receptors. The 30-year duration is the national 95th percentile of the duration that persons reside at one location. However, as a point of reference, the Guidance suggests that both 9-year exposure duration and 70-year exposure duration should be noted. A 70-year exposure assumes that a person never moves from the location he or she was born. The 9-year exposure represents the national median duration that a person resides in the same location. The 9-year and 70-year cancer risk is calculated as follows:

Residential 9-Year Exposure DPM Cancer Risk =

$$[(C_{air} \times 361 \times 350/365 \times 10^{-6} \times 1.1 \times 10) \times (0.25 \text{ yrs} / 70 \text{ yrs}) \times 1.0]_{\text{third trimester}} + \\ [(C_{air} \times 1090 \times 350/365 \times 10^{-6} \times 1.1 \times 10) \times (2 \text{ yrs} / 70 \text{ yrs}) \times 1.0]_{0 \text{ to } <2 \text{ yrs}} + \\ [(C_{air} \times 861 \times 350/365 \times 10^{-6} \times 1.1 \times 3) \times (7 \text{ yrs} / 70 \text{ yrs}) \times 1.0]_{2 \text{ to } <9 \text{ yrs}}$$

Residential 70-Year Exposure DPM Cancer Risk =

$$[(C_{air} \times 361 \times 350/365 \times 10^{-6} \times 1.1 \times 10) \times (0.25 \text{ yrs} / 70 \text{ yrs}) \times 1.0]_{\text{third trimester}} + \\ [(C_{air} \times 1090 \times 350/365 \times 10^{-6} \times 1.1 \times 10) \times (2 \text{ yrs} / 70 \text{ yrs}) \times 1.0]_{0 \text{ to } <2 \text{ yrs}} + \\ [(C_{air} \times 745 \times 350/365 \times 10^{-6} \times 1.1 \times 3) \times (14 \text{ yrs} / 70 \text{ yrs}) \times 1.0]_{2 \text{ to } <16 \text{ yrs}} + \\ [(C_{air} \times 290 \times 350/365 \times 10^{-6} \times 1.1 \times 1) \times (54 \text{ yrs} / 70 \text{ yrs}) \times 0.73]_{16 \text{ to } <70 \text{ yrs}}$$

To account for the additional air toxics, the DPM cancer risk was multiplied by a factor of 1.05 to arrive at the total risk.

2.6.2 Worker Cancer Risk

The same equations that are used for calculating residential cancer risk are used for calculating worker risk, however some of the parameters change to reflect worker versus residential exposure. For workers, it is assumed that a person works at the same place for 25 years, starting at age 16. It is also assumed the worker could be pregnant while working, so the third trimester exposure is included in the risk calculation. The 95th percentile breathing rates for residents are different than for workers, which for workers are 240 L/kg-day for the third trimester and 230 L/kg-day for age 16 to 70 (Guidance Section 5.4.1.2). No "Fraction of Time at Home factor is used for workers; but the EF is assumed to be 5 days per week, 50 weeks per year, or 250 days out of 365. Accordingly, the worker cancer risk is calculated as follows:

Worker 25-Year Exposure DPM Cancer Risk =

$$[(C_{air} \times 240 \times 250/365 \times 10^{-6} \times 1.1 \times 10) \times (0.25 \text{ yrs} / 70 \text{ yrs})]_{\text{third trimester}} + \\ [(C_{air} \times 230 \times 250/365 \times 10^{-6} \times 1.1 \times 1) \times (25 \text{ yrs} / 70 \text{ yrs})]_{16 \text{ to } <70 \text{ yrs}}$$

The worker cancer risk formula applies to all types of workers, including workers who may be working at sensitive receptors such as day care centers. To account for the additional air toxics, the DPM cancer risk was multiplied by a factor of 1.05 to arrive at the total risk.

2.6.3 Day Care Center Children Cancer Risk

For children who attend a day care center, cancer risk is calculated similarly to residential with factors in the equations changed to reflect children and day care exposure. The Guidance recommends a breathing rate of 1200 L/kg-day for age 0 to <2 years and 640 L/kg-day for 2 to <9 years (Guidance Section 5.4.1.3) for children at day care centers. The duration is assumed to be 250 days per year for 6 years. The formula for day care center children cancer risk is as follows:

Day Care Center Children 6-year DPM Cancer Risk =

$$[(C_{\text{air}} \times 1200 \times 250/365 \times 10^{-6} \times 1.1 \times 10) \times (2 \text{ yrs} / 70 \text{ yrs})]_{0 \text{ to } <2 \text{ years}} + \\ [(C_{\text{air}} \times 640 \times 250/365 \times 10^{-6} \times 1.1 \times 3) \times (4 \text{ yrs} / 70 \text{ yrs})]_{2 \text{ to } <6 \text{ yrs}}$$

To account for the additional air toxics, the DPM cancer risk was multiplied by a factor of 1.05 to arrive at the total risk.

2.6.4 School Children Cancer Risk

For children who attend elementary, middle or high school, cancer risk is calculated similarly to the day care center children. Elementary school duration is 7 years (kindergarten through sixth grade), middle school is 2 or 3 years (seventh through eighth or ninth grade) and high school is 3 or 4 years (ninth or tenth grade through twelfth grade). The longest duration and the largest Age Sensitivity Factors occur for elementary school, and thus elementary school exposure was used as the worst-case. It was assumed that children attend school 5 days per week for 36 weeks less 3 weeks of vacation, or 165 days per year. The Guidance recommends a school children breathing rate of 520 L/kg-day (Guidance Section 5.4.1.3). A worst case calculation was used for all school children as follows:

School Children 7-year DPM Cancer Risk =

$$[(C_{\text{air}} \times 520 \times 165/365 \times 10^{-6} \times 1.1 \times 3) \times (7 \text{ yrs} / 70 \text{ yrs})]_{2 \text{ to } <16 \text{ years}}$$

To account for the additional air toxics, the DPM cancer risk was multiplied by a factor of 1.05 to arrive at the total risk.

2.6.5 Senior Center Cancer Risk

The cancer risk for senior center residents was calculated similarly to the residential cancer risk, although it was assumed that a senior center resident did not arrive at the center full time until the person was over the age of 30 and that a person would not reside at the same senior center for more than 30 years. It was also conservatively assumed that the person never left the senior center, so the Exposure Frequency was continuous over 365 days and there is no Fraction of Time at Home factor. The risk was calculated as follows:

Senior Center 30-Year Exposure DPM Cancer Risk =

$$[(C_{air} \times 290 \times 365/365 \times 10^{-6} \times 1.1 \times 1) \times (30 \text{ yrs} / 70 \text{ yrs})]_{30 \text{ to } <70 \text{ yrs}}$$

To account for the additional air toxics, the DPM cancer risk was multiplied by a factor of 1.05 to arrive at the total risk.

2.6.6 Hot Spots Analysis and Reporting Program (HARP)

CARB has published a computer model that can automatically calculate the cancer risk for residential and worker exposures. This program is called the Hot Spots Analysis and Reporting Program Version 2 (HARP 2). The above equations were for the inhalation pathway only, but it is easy to see that calculating cancer risk for chemicals that have multi-pathway exposures can become quite complex. Therefore, HARP 2 automates the calculations using the above equations and additional equations for all chemicals and pathways. Some regulatory agencies require air toxic health risk assessments be conducted with HARP 2. For DPM, HARP 2 will yield the same results (accounting for round-off differences) as the above equations. To confirm that the spreadsheet calculations performed in this health risk assessment match the results that would be obtained with HARP 2, the HARP 2 model was run for one of the transportation segments and the results compared to the spreadsheet calculations as discussed in Section 3.3.

3 HEALTH RISK ASSESSMENT RESULTS

3.1 MAXIMUM RESIDENTIAL AND WORKER RISKS

The maximum exposed individual resident (MEIR) and the maximum exposed individual worker risk results for each of the segments for each of the evaluated simulations are summarized in Tables 3-1 through 3-4 (*Maximum Exposed Individual Residential Cancer Risk for 30-year, 9-year, and 70-year Exposure*, respectively). The calculated results include the 5 percent increase to DPM-only risk to account for additional air toxics, which include acetaldehyde, benzene, 1,3-butadiene, and formaldehyde. The results are expressed as the incremental cancer risk per million exposed persons. The residential risk for Simulations 2 through 5 ranges from 93 in a million to 9 in a million cancer risk for 30-year exposure (Table 3-1), 66 in a million to 6 in a million cancer risk for 9-year exposure (Table 3-2), and 106 in a million to 10 in a million cancer risk for 70-year exposure (Table 3-3). The exposed worker risk for Simulations 2 through 5 ranges from 7 in a million to 1 in a million cancer risk (Table 3-4). Risk calculation details are provided in Appendix D, and output files showing all of the receptor concentrations are contained in Appendix F.

16	VEN US-101 TO	Ventura / Thousand Oaks	46	3	3	3	3

The 30-year exposure residential cancer risk is greater than the worker cancer risk in all segments and evaluation simulations (Tables 3-2 and 3-4). The largest MEIR cancer risk occurs for Segment 8, ORA I-405. For this transportation segment, Simulation 1 (Existing Conditions) causes the greatest cancer risk, and Simulation 4 (2012 RTP/SCS Update with Local Input Alternative) causes the least cancer risk. For 30-year maximum residential exposure at the ORA I-405 transportation segment, Simulation 4 is about 8 percent of the Simulation 1.

The 9-year exposure cancer risk is about 30 percent less than the 30-year exposure cancer risk (Tables 3-1 and 3-2). The 70-year exposure cancer risk is about 14 percent greater than the 30-year exposure cancer risk (Tables 3-1 and 3-3).

3.2 MAXIMUM SENSITIVE RECEPTOR RISKS

Three types of sensitive receptors were evaluated where the calculation of risk differs from a residential or a worker receptor: day care centers, schools, and senior centers. Other sensitive receptors such as churches and hospitals were represented either by a worker receptor (e.g., the risk to hospital workers or church workers are the same as other workers) or the duration of exposure is much less than at a senior center (e.g., patients at a hospital do not stay in the hospital for 30 years as it was assumed for senior centers and persons attending church spend much less time at church than at home). The risks associated with these receptors is shown in Tables 3-5 through 3-7 (*Maximum Exposed Cancer Risk [cancer risk per million exposed persons] for Day Care Center Children, School Children, and Senior Center, respectively*)

The risk at all other sensitive receptors are the same or less than those shown in the tables. It is important to note that not all segments had all three types of sensitive receptors present within 1000 meters of the transportation segment. In that case, an entry of "NR" (no receptor) was made in the tables.

15	VEN US-101 SB	Ventura / San Buenaventura	27	2	2	2	2
16	VEN US-101 TO	Ventura / Thousand Oaks	17	1	1	1	1

NR = No sensitive receptor of this type located within 1000 meters of the transportation segment.

Tables 3-5 through 3-7 show that sensitive receptor cancer risk is always less than the MEIR cancer risk shown in Table 3-1 for all segments and evaluation simulations. The largest sensitive receptor cancer risk value occurs for Segment 5, LA SR-60 DB for the day care center type of sensitive receptor. For this receptor, Simulation 1 – Existing Conditions causes the greatest cancer risk and Simulation 4 – 2012 RTP/SCS with Local Input Alternatives, the least risk. The maximum sensitive receptor risk for existing conditions is at a day care center near the LA SR-60 DB, where the risk for Simulation 4 is about 1.3 percent of the risk for Simulation 1.

3.3 HARP 2 MODEL RESULTS

The HARP 2 risk assessment model was used to verify the workbook risk calculations prepared using one segment and simulation for comparison; Segment 8, Interstate 405 in the Seal Beach area (ORA I-405) and Evaluation Simulation 1 – Existing Conditions was randomly chosen. The results for the MEIR compared to the spreadsheet calculation results are shown in Table 3-8 (*Comparison of HARP 2 and Spreadsheet Calculation Results*). The spreadsheet calculation results come from Tables 3-1, 3-2, and 3-3 and the HARP 2 electronic copies of the HARP 2 model results are contained in Appendix F. Table 3-8 demonstrates that the calculation procedures used herein match the HARP 2 model results within round-off differences and the spreadsheet calculations are slightly greater than the HARP 2 results. Both the HARP 2 and spreadsheet calculation risk for DPM shown in Table 3-8 were increased by 5 percent to account for the additional air toxics of acetaldehyde, benzene, 1,3-butadiene, and formaldehyde.

Table 3-8
Comparison of HARP 2 and Spreadsheet Calculation Results

RESIDENTIAL EXPOSURE DURATION	HARP 2 CANCER RISK (per million)	CALCULATION USED HEREIN CANCER RISK (per million)	PERCENT DIFFERENCE OVER HARP 2
30-Year	935	939	+0.4%
9-year	665	667	+0.3%
70-year	1,060	1,070	+0.9%

3.4 MAXIMUM HYPOTHETICAL RECEPTOR RISKS

Two sets of hypothetical receptors were evaluated for two of the Transportation Segments.

The first set of hypothetical receptors was to assume that any receptor type could be located at the maximum impact point for Segment 8, ORA I-405 (Interstate 405 in the Seal Beach area). This maximum impact point was chosen as it was the highest risk receptor from any of the transportation segments. The maximum impact point was actually a residence, but hypothetically, there could be a worker receptor, a day care center, a school, or a senior center at such a receptor. In order to evaluate the range of possible risk, the risk for each of those receptor types was calculated assuming that the concentration was the maximum of any of the modeled receptors. The results are shown in Table 3-9 (Hypothetical Maximum Impact for Any Receptor Type [cancer risk per million exposed persons]).

Table 3-9

**Hypothetical Maximum Impact for Any Receptor Type
(cancer risk per million exposed persons)**

RECEPTOR TYPE	SIMULATION 1 (EXISTING CONDITIONS)	SIMULATION 2 (NO PROJECT ALTERNATIVE)	SIMULATION 3 (PROPOSED PROJECT)	SIMULATION 4 (2012 RTP/SCS WITH LOCAL INPUT ALTERNATIVE)	SIMULATION 5 (INTENSIFIED LAND USE ALTERNATIVE)
30-year Residential	1,142	81	78	78	78
Worker	90	6	6	6	6
Day Care Center Children	450	32	31	31	31
School Children	102	7	7	7	7
Senior Center	180	13	12	12	12

The results in Table 3-9 indicate 1) that the maximum risk for any receptor in the SCAG Region for any of the Simulations 2 through 5, is on the order of less than 10 percent when compared to Simulation 1- Existing Conditions and 2) that residential risk is always greater than the other risk types.

The second set of hypothetical receptors evaluated was to assume that there is a residential receptor every 100 meters away from a transportation segment out to a distance of 1300 meters. The purpose of this analysis is to show how quickly the potential cancer risk decreases with

distance away from the transportation segment. For this analysis, Segment 4, LA I-710 in the Compton area, and Simulation 1 – Existing Conditions, was evaluated assuming that there were residential receptors starting at 25 meters from the freeway edge, 50 meters, 100 meters, and then every 100 meters out to 1300 meters away from the freeway. The results of the analysis are shown in Table 3-10 (*Hypothetical Maximum Impact for 30-year Residential Receptors as a Function of Distance for Existing Conditions and LA I-710 [cancer risk per million exposed persons]*). This analysis assumed residential receptors because for a given impact concentration residential cancer risk is the largest of any receptor type.

Table 3-10

**Hypothetical Maximum Impact for 30-year Residential Receptors
as a Function of Distance for Existing Conditions and LA I-710
(cancer risk per million exposed persons)**

DISTANCE FROM FREEWAY (meters)	MAXIMUM IMPACT CONCENTRATION ($\mu\text{g}/\text{m}^3$)	ASSUMED MEIR CANCER RISK HRA SIMULATION 1 (DPM + 5% for other chemicals)	RATIO OF ASSUMED MEIR CANCER RISK TO RISK MODELED AT 100 METERS
25*	2.264	2,058	2.43
50*	1.463	1,330	1.57
100	0.932	847	1.00
200	0.516	469	0.55
300	0.349	317	0.37
400	0.257	234	0.28
500	0.199	181	0.21
600	0.160	145	0.17
700	0.131	119	0.14
800	0.110	100	0.12
900	0.0933	85	0.10
1000	0.0804	73	0.09
1100	0.0701	64	0.08
1200	0.0618	56	0.07
1300	0.0549	50	0.06

*Note that the AERMOD model was run only for 100-meter spacing, so the 25 and 50-meter results were interpolated using the exponential form of dispersion. The interpolation is based on Figure 1-1 of the CARB Air Quality and Land Use Handbook.⁸

Table 3-10 shows that potential cancer risk rapidly decreases with distance away from the freeway. The potential cancer risk to a resident 500 meters away from the freeway is only 21 percent of the risk at 100 meters and less than a tenth the risk at 25 meters. The ratios shown in Table 3-10 can be used to evaluate potential hypothetical receptors for other freeways as well.

⁸ Air Quality and Land Use Handbook, April 2005. California Air Resources Board.

This is because dispersion very near (i.e., a few hundred meters or less) an emission source (i.e., the freeway) is nearly independent of meteorological conditions.

3.5 HEALTH RISK COMPARISON TO THE 2012-2035 RTP/SCS PEIR

As stated, eight of the transportation segments evaluated were the same segments that were evaluated in the 2012-2035 RTP/SCS PEIR. Table 3-11 shows the residential health risks presented in the 2012-2035 RTP/SCS PEIR for the 2035 Preferred Plan compared to the No Project Alternative. The cancer risk shown in Table 3-11 (*Health Risk Comparison to the 2012-2035 RTP/SCS PEIR*) is a 70-year residential risk because the 2012-2035 RTP/SCS PEIR risk assessment methodology was based on 70-year exposure. The residential cancer risk for the No Project Alternative has decreased from the 2012-2035 RTP/SCS PEIR.

Table 3-11
Health Risk Comparison to the 2012-2035 RTP/SCS PEIR

SEG NO.	TRANSPORTATION SEGMENT	COUNTY / REGION	2012-2035 RTP/SCS PEIR RESIDENTIAL 70-YEAR CANCER RISK (per million)	NO PROJECT ALTERNATIVE RESIDENTIAL 70-YEAR CANCER RISK (per million)
1	IMP I-8	Imperial / El Centro	399	51
4	LA I-710	Los Angeles / Compton	475	66
5	LA SR-60 DB	Los Angeles / Diamond Bar	536	106
8	ORA I-405	Orange / Seal Beach	462	93
11	RIV SR-91	Riverside / Corona	668	73
12	SB I-15 ONT	San Bernardino / Ontario	354	52
14	SB SR-60	San Bernardino / Ontario	714	51
16	VEN US-101 TO	Ventura / Thousand Oaks	199	72

The differences shown in Table 3-11 are due to two primary reasons. First, the emission factors for HDDT projected by the current version of the EMFAC model for 2040 are much less (on the order of 95 percent less) than the emission factors used in the 2012-2035 RTP/SCS PEIR for 2035. The emission factors from the previous version of EMFAC used for the 2012-2035 PEIR did not account for the dramatic decrease in diesel emissions as a result of the CARB diesel exhaust reduction program and the effectiveness of the new DPM control technologies. Secondly, the vehicle mileage projected by the current SCAG transportation demand model is different than

what was projected in the 2012-2035 RTP/SCS PEIR because a more updated 2012 Base Year transportation network is being used for this 2016 RTP/SCS. As noted above, this 2012 Base Year transportation network includes the transportation projects included in the 2015 FTIP, adopted in September 2014, and transportation projects in the 2012-2035 RTP/SCS as amended in September 2014. For example, the HD VMT for Segment 8, ORA I-405 was projected in the 2012-2035 RTP/SCS PEIR to be about 50,000 miles per day in 2035, while the current model for the No Project Alternative predicts about 68,000 miles per day in 2040 for heavy duty diesel truck traffic. The combined result of these differences show a decrease in the overall risk to residential, worker and sensitive receptors in the current predictions when compared with the previous analysis.

3.6 ADDITIONAL HEALTH RISKS FROM VEHICLE EMISSIONS

For this analysis, cancer risk was used as a surrogate for all of the potential health effects related to vehicle emissions. Vehicles emit many additional pollutants in addition to DPM, including criteria pollutants, the aforementioned key air toxics (i.e., acetaldehyde, benzene, 1,3-butadiene, formaldehyde), and other minor air toxic emissions. These compounds cause not only potential carcinogenic health effects but also non-carcinogenic acute (short-term) and chronic (long-term) health effects to the respiratory system, central nervous system, eyes, and immune system, and others. The non-carcinogenic effects are assessed by comparing the impact concentration to published Reference Exposure Levels (RELs). If the impact concentration is less than the REL, then potential non-carcinogenic health effects are not likely to occur. For vehicle emissions, the potential for carcinogenic effects is much greater than for non-cancer effects. This is most easily illustrated through examination of the REL for diesel exhaust. The REL for diesel exhaust published by CARB⁹ is 5 ug/m³. This is a chronic REL. If a person were exposed to diesel exhaust particulate at a chronic concentration of 5 ug/m³, the residential cancer risk would be 4,000 in a million; a value much greater than the modeled cancer risk due to vehicle traffic on the worst-case transportation segments. Therefore, potential cancer risk is an adequate surrogate for all of the potential health effects due to vehicle emissions.

3.7 OTHER RISK ASSESSMENTS IN THE SOUTH COAST BASIN

The cancer risk calculated for the 16 transportation segments can be compared to other regional estimates of cancer risk. One of the most comprehensive such studies is the Multiple Air Toxics

⁹ OEHHA Toxicity Criteria Database, Diesel Exhaust Particulate as of September 11, 2015. Available at <http://oehha.ca.gov/tcdb/index.asp>.

Exposure Study in the South Coast Air Basin, May 2015 (MATES-IV)¹⁰ The MATES-IV study estimated basin-wide average cancer risk with actual monitored data at 10 sites in calendar year 2012. The basin-wide cancer risk calculated from the 2012 monitoring data and using the current (2015) risk assessment methodology (the same methodology used herein) for 30-year residential exposure was 1,023 in a million¹¹ caused mostly by DPM. The MATES-IV study also showed that cancer risk was greatest near major freeways and transportation corridors¹². Note that the MATES-IV study did not estimate future (2040) risk, but due to the dramatic reduction in DPM emissions from HDDT, the basin-wide cancer risk should be much less than found in 2015.

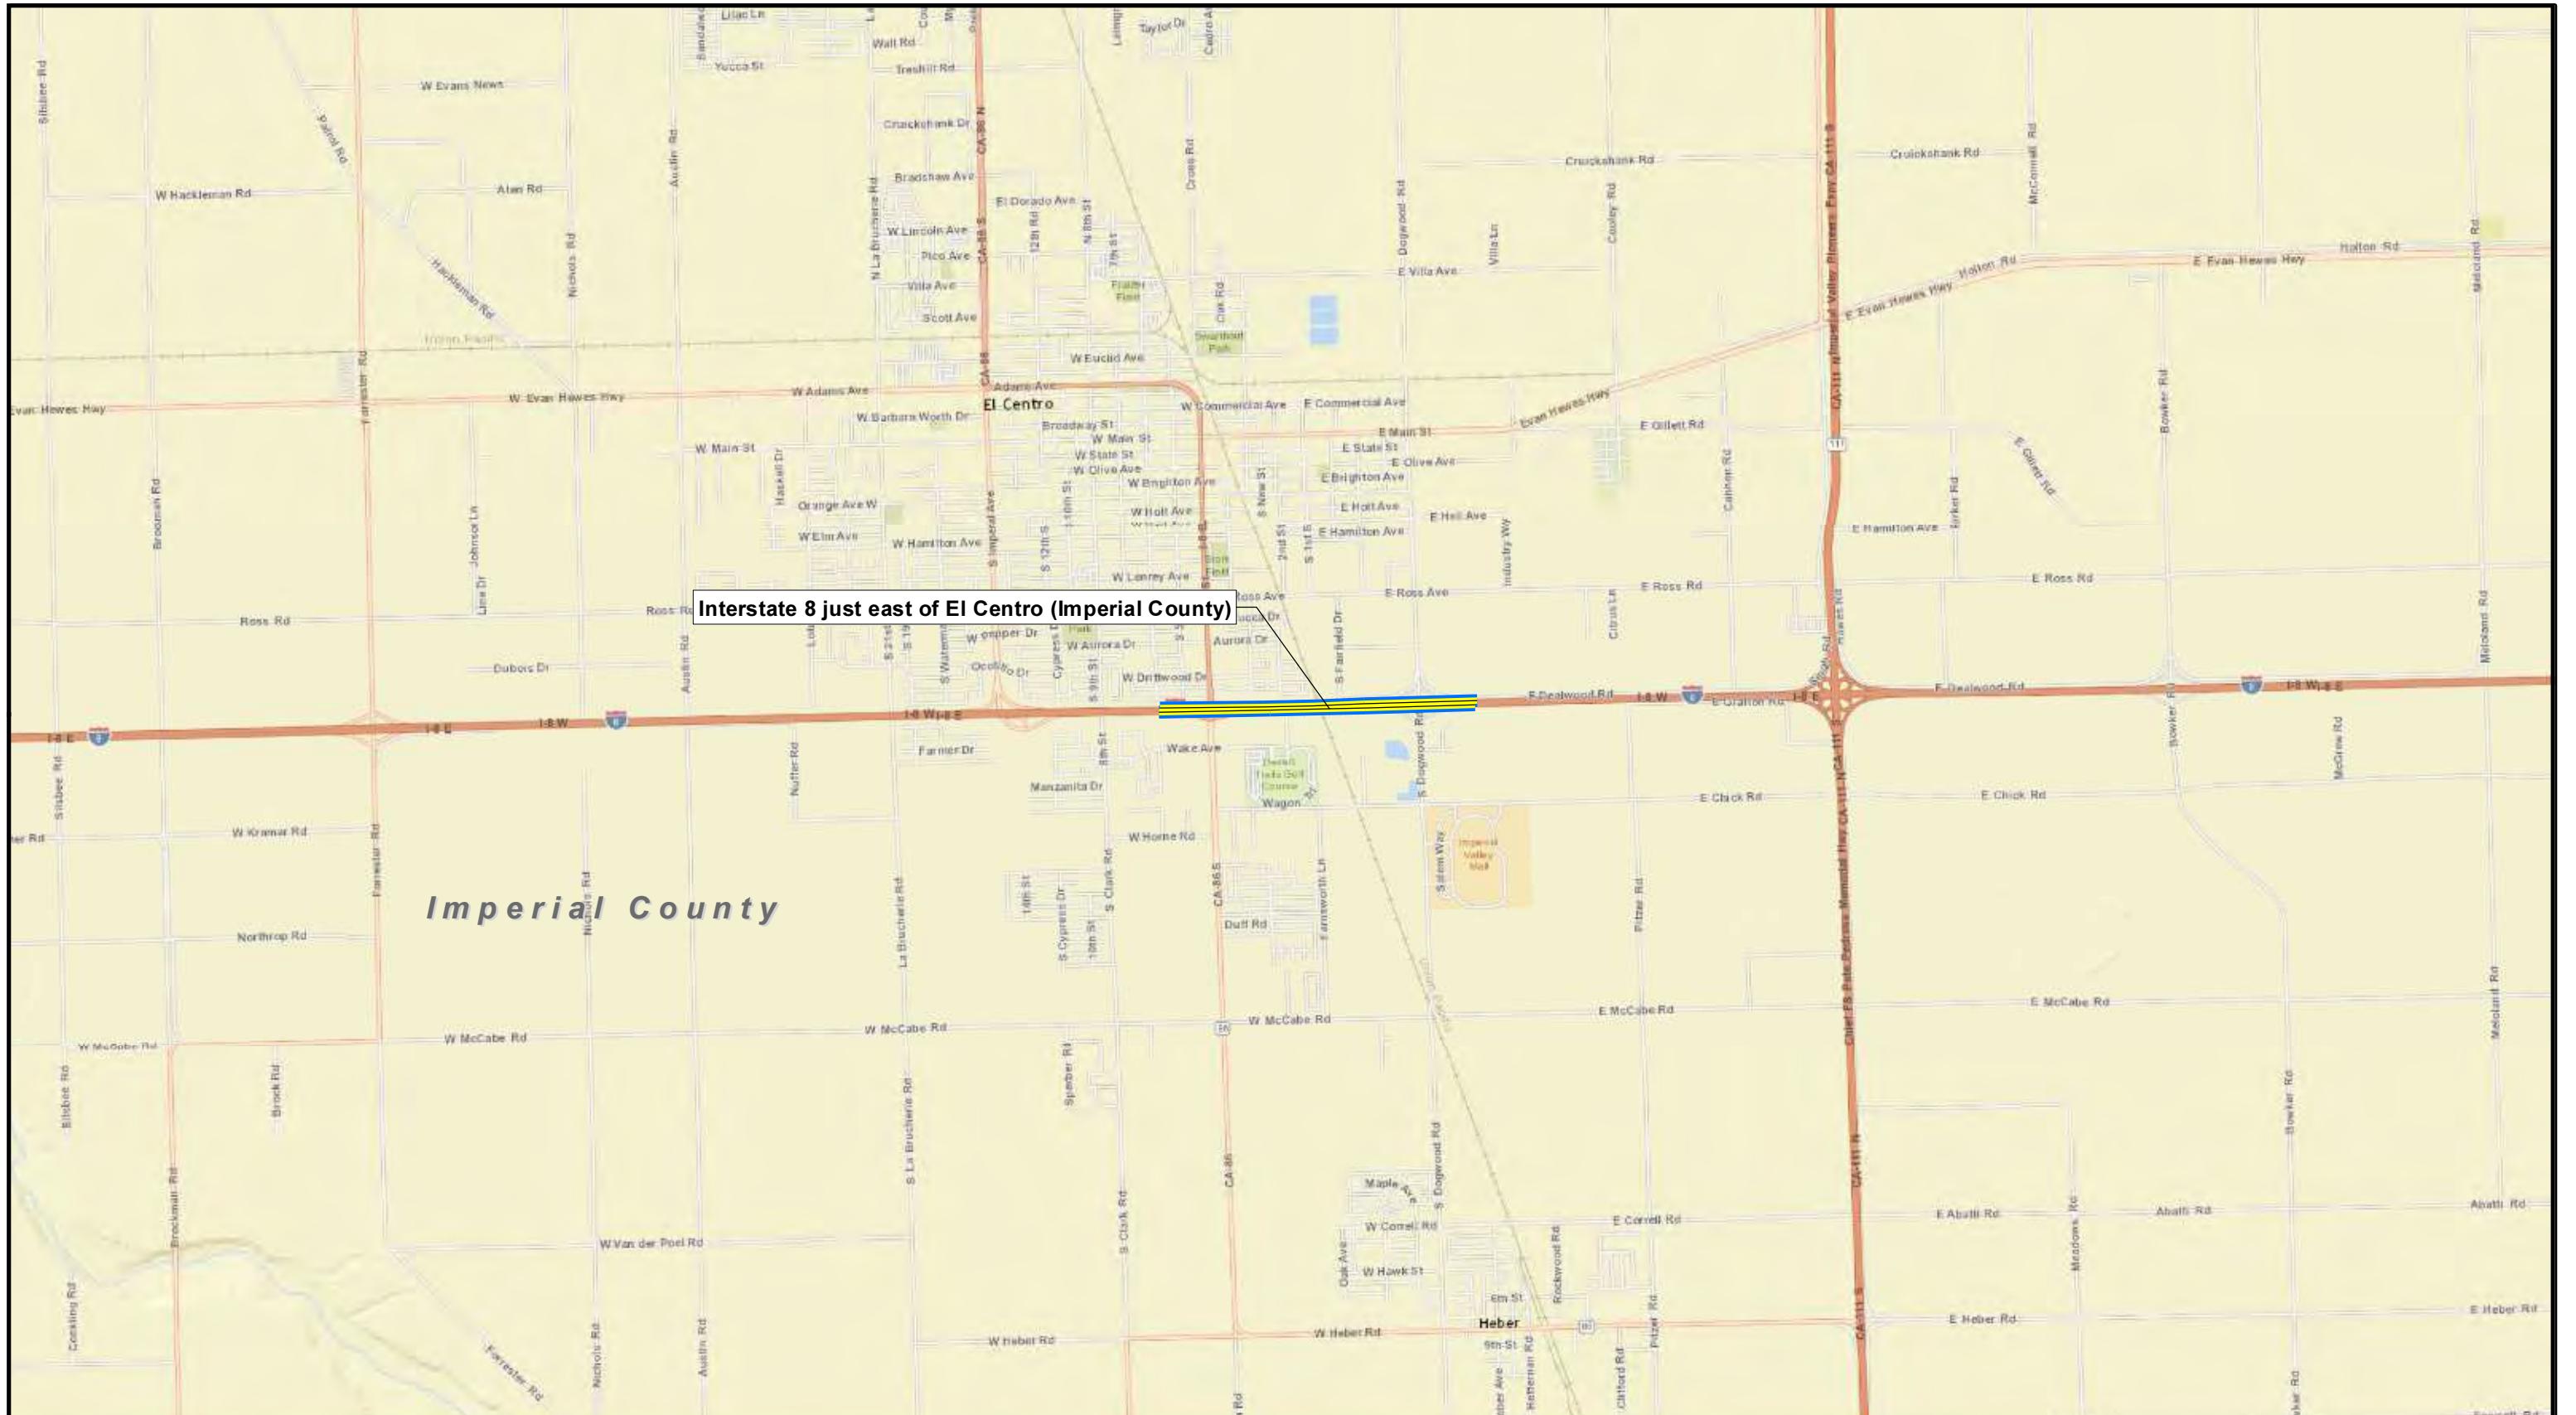

¹⁰ Final Report, Multiple Air Toxics Exposure Study in the South Coast Air Basin, MATES-IV, May 2015. South Coast Air Quality Management District, available at <http://www.aqmd.gov/home/library/air-quality-data-studies/health-studies>, last accessed September 2015.

APPENDIX D

Health Risk Calculations for Each Transportation Segment and Evaluation Simulation

Example Risk Calculations
Diesel Exhaust HRA for SCAG 2016-2040 RTP/SCS

References are to the OEHAA Air Toxic Hot Spots Program, Risk Assessment Guidelines, February 2015; unless otherwise noted.

1.0 Residential Risk Calculation

PMI Residential Concentration (Conc)	0.0123	ug/m3	MEIR	(Example Concentration)	
DPM Cancer Potency Factor (CPF)	1.1	(mg/kg-day) ⁻¹	from http://oehha.ca.gov/air/hot_spots/2009/AppendixA.pdf		
Breathing Rates are 95th Percentile (Tbl 5.6)					
Breathing Rate 3rd Trimester	361	L/kg-day	1 Fraction Home 3rd Trimester		10
Breathing Rate 0 to <2 yrs	1090	L/kg-day	1 Fraction Home 0 to <2 yrs		10
Breathing Rate 2 to <16 yrs	745	L/kg-day	1 Fraction Home 2 to <16 yrs		3
Breathing Rate 16 to <70 yrs	290	L/kg-day	0.73 Fraction Home 16 to <70 yrs		1
Breathing Rate 2 to <9 yrs	861	L/kg-day	1 Fraction Home 2 to <9 yrs		3
Breathing Rate 16 to <30 yrs	335	L/kg-day	0.73 Fraction Home 16 to <30 yrs		1
Cancer Risk 3rd Trimester	1.67E-07	Conc x Breathe Rate x 1E-06 x 350/365 x Fraction Home x CPF x 0.25/70 x Age Sensitivity			
Cancer Risk 0 to <2 yrs	4.04E-06	Conc x Breathe Rate x 1E-06 x 350/365 x Fraction Home x CPF x 2/70 x Age Sensitivity			
Cancer Risk 2 to <16 yrs	5.80E-06	Conc x Breathe Rate x 1E-06 x 350/365 x Fraction Home x CPF x 14/70 x Age Sensitivity			
Cancer Risk 16 to <70 yrs	2.12E-06	Conc x Breathe Rate x 1E-06 x 350/365 x Fraction Home x CPF x 54/70 x Age Sensitivity			
Cancer Risk 2 to <9 yrs	3.35E-06	Conc x Breathe Rate x 1E-06 x 350/365 x Fraction Home x CPF x 7/70 x Age Sensitivity			
Cancer Risk 16 to <30 yrs	6.35E-07	Conc x Breathe Rate x 1E-06 x 350/365 x Fraction Home x CPF x 14/70 x Age Sensitivity			
9-year Risk	7.56E-06	3rd Trimester + 0 to 2 year risk + 2 to 9 year risk			
30-year Risk	1.06E-05	3rd Trimester + 0 to 2 year risk + 2 to 16 year risk + 16 to 30 year risk			
70-year Risk	1.21E-05	3rd Trimester + 0 to 2 year risk + 2 to 16 year risk + 16 to 70 year risk			

2.0 Off-Site Worker Risk Calculation

Assumes that there a worker could be pregnant while working.

25-year working duration at a single location (starting at age 16) per Guidance Section 8.2.4.

Includes day care, hospital, senior center, school workers.

PMI Worker Concentration (Conc)	0.0741	ug/m3	MEIW	(Example Concentration)	
Breathing Rates are 95th Percentile					
Breathing Rate 3rd Trimester	240	L/kg-day	Tbl 5.8, mod. intensity, Age 16-30 per note a.		10
8-hour Breathing Rate 16 to 70 years	230	L/kg-day	Tbl 5.8, mod. intensity, Age 16-70		1
Age Sensitivity Factors (Tbl 8.3)					
Cancer Risk 3rd Trimester	4.79E-07	Conc x Breathe Rate x 1E-06 x 250/365 x CPF x 0.25/70 x Age Sensitivity [5 days/wk x 50 wk/yr]			
Cancer Risk 16 to <70 yrs	4.59E-06	Conc x Breathe Rate x 1E-06 x 250/365 x CPF x 25/70 x Age Sensitivity [5 days/wk x 50 wk/yr]			
Cancer Risk for 25 working years	5.06E-06	3rd Trimester + 25 years of risk			

Example Risk Calculations
Diesel Exhaust HRA for SCAG 2016-2040 RTP/SCS

3.0 Day Care Center Children

Assumes child is at the Day Care Center for 0 to 6 years.
Day Care Center workers included in Off-Site Worker calculation.

Day Care Concentration (Conc)	0.0532	ug/m ³	(Example Concentration)	
Breathing Rates are 95th Percentile				
8-hour Breathing Rate 0 to <2 years	1200	L/kg-day	Tbl 5.8, mod. intensity, Age 0 to <2 per Sect. 5.4.1.3	10
8-hour Breathing Rate 2 to <9 years	640	L/kg-day	Tbl 5.8, mod. intensity, Age 2 to <9 per Sect. 5.4.1.3	3
Cancer Risk 0 to <2 yrs	1.37E-05		Conc x Breathe Rate x 1E-06 x 250/365 x CPF x 2/70 x Age Sensitivity [5 days/wk x 50 wk/yr]	
Cancer Risk 2 to 6 yrs	4.40E-06		Conc x Breathe Rate x 1E-06 x 250/365 x CPF x 4/70 x Age Sensitivity [5 days/wk x 50 wk/yr]	
Cancer Risk for 6 years Day Care	1.81E-05		<i>0 to <2 year risk + 2 to 6 year risk</i>	

4.0 Schools (Elementary, Middle school, High school)

Assumes maximum exposure occurs at an elementary school Kindergarten (Age 5) through 6th Grade, so total 7 years.
School workers included in Off-Site Worker calculation.

School Concentration (Conc)	0.1256	ug/m ³	(Example Concentration)	
Breathing Rates are 95th Percentile				
8-hour Breathing Rate 2 to <16 years	520	L/kg-day	Tbl 5.8, mod. intensity, Age 2 to <16 per Sect. 5.4.1.3	3
Cancer Risk K through 6 Grade	9.74E-06		Conc x Breathe Rate x 1E-06 x 165/365 x CPF x 7/70 x Age Sensitivity [5 days/wk x 36 wk/yr minus 3 weeks vacation]	
Cancer Risk for 7 years School	9.74E-06		<i>7 year total risk, Age 5 to <12</i>	

5.0 Senior Center Residents

Assume resident is at a Senior Center for 30 years and enters after age 16 and does not bear a child.
Senior Center workers included in Off-Site Worker calculation.

Senior Center Concentration (Conc)	0.0853	ug/m ³	(Example Concentration)	
Breathing Rates are 95th Percentile (Tbl 5.6)				
Breathing Rate 16 to <70 yrs	290	L/kg-day		1
Cancer Risk 16 to <70 yrs	1.17E-05		Conc x Breathe Rate x 1E-06 x 365/365 x CPF x 30/70 x Age Sensitivity	
Senior Center 40-year Risk	1.17E-05		<i>30 year total risk</i>	

			Age
		Fraction of Time at Home	Sensitivity Factors
Residential Breathing Rates are 95th Percentile			
Breathing Rate 3rd Trimester	361	L/kg-day	1 10
Breathing Rate 0 to <2 yrs	1090	L/kg-day	1 10
Breathing Rate 2 to <16 yrs	745	L/kg-day	1 3
Breathing Rate 16 to <70 yrs	290	L/kg-day	0.73 1
Breathing Rate 2 to <9 yrs	861	L/kg-day	1 3
Breathing Rate 16 to <30 yrs	335	L/kg-day	0.73 1
Off-site Worker Breathing Rates are 95th Percentile			
Breathing Rate 3rd Trimester	240	L/kg-day	10
8-hour Breathing Rate 16 to 70 years	230	L/kg-day	1
Day Care and School Breathing Rates are 95th Percentile			
8-hour Breathing Rate 0 to <2 years	1200	L/kg-day	10
8-hour Breathing Rate 2 to <9 years	640	L/kg-day	3
8-hour Breathing Rate 2 to <16 years	520	L/kg-day	3
DPM Cancer Potency	1.1	(mg/kg-day) ⁻¹	
Percentage Risk Increase over DPM	5%	For additional compounds emitted from vehicles (acetaldehyde, benzene, 1,3-butadiene, formaldehyde)	

NR = No Receptor for the category within 1000 m of the freeway.

Notes:

1. The I-15 MEIR is an assumed residential receptor at about 100 meters from the freeway because although there are no residential receptors near the segment modeled, there are a number of nearby residential receptors only 2 miles north of the modeled segment and traffic volumes are expected to be similar on I-15 where there are nearby residents.

Scenario 2: 2040 Base Line (2040BL), Future Conditions
Diesel Exhaust HRA for SCAG 2016-2040 RTP/SCS

			Age		
		Fraction of Time at Home	Sensitivity		
			Factors		
Residential Breathing Rates are 95th Percentile					
Breathing Rate 3rd Trimester	361	L/kg-day	1	10	
Breathing Rate 0 to <2 yrs	1090	L/kg-day	1	10	
Breathing Rate 2 to <16 yrs	745	L/kg-day	1	3	
Breathing Rate 16 to <70 yrs	290	L/kg-day	0.73	1	
Breathing Rate 2 to <9 yrs	861	L/kg-day	1	3	
Breathing Rate 16 to <30 yrs	335	L/kg-day	0.73	1	
Off-site Worker Breathing Rates are 95th Percentile					
Breathing Rate 3rd Trimester	240	L/kg-day		10	
8-hour Breathing Rate 16 to 70 years	230	L/kg-day		1	
Day Care and School Breathing Rates are 95th Percentile					
8-hour Breathing Rate 0 to <2 years	1200	L/kg-day		10	
8-hour Breathing Rate 2 to <9 years	640	L/kg-day		3	
8-hour Breathing Rate 2 to <16 years	520	L/kg-day		3	
DPM Cancer Potency	1.1	(mg/kg-day)^{-1}			
Percentage Risk Increase over DPM	5%				
For additional compounds emitted from vehicles (acetaldehyde, benzene, 1,3-butadiene, formaldehyde)					

NR = No Receptor for the category within 1000 m of the freeway.

Notes:

1. The I-15 MEIR is an assumed residential receptor at about 100 meters from the freeway because although there are no residential receptors near the segment modeled, there are a number of nearby residential receptors only 2 miles north of the modeled segment and traffic volumes are expected to be similar on I-15 where there are nearby residents.

Scenario 3: 2040 Plan Scenario 2 (2040PLSC2), Future Conditions under the No Project Alternative
Diesel Exhaust HRA for SCAG 2016-2040 RTP/SCS

		Age	
		Fraction of Time at Home	Sensitivity Factors
Residential Breathing Rates are 95th Percentile			
Breathing Rate 3rd Trimester	361	L/kg-day	1 10
Breathing Rate 0 to <2 yrs	1090	L/kg-day	1 10
Breathing Rate 2 to <16 yrs	745	L/kg-day	1 3
Breathing Rate 16 to <70 yrs	290	L/kg-day	0.73 1
Breathing Rate 2 to <9 yrs	861	L/kg-day	1 3
Breathing Rate 16 to <30 yrs	335	L/kg-day	0.73 1
Off-site Worker Breathing Rates are 95th Percentile			
Breathing Rate 3rd Trimester	240	L/kg-day	10
8-hour Breathing Rate 16 to 70 years	230	L/kg-day	1
Day Care and School Breathing Rates are 95th Percentile			
8-hour Breathing Rate 0 to <2 years	1200	L/kg-day	10
8-hour Breathing Rate 2 to <9 years	640	L/kg-day	3
8-hour Breathing Rate 2 to <16 years	520	L/kg-day	3
DPM Cancer Potency	1.1	(mg/kg-day) ⁻¹	
Percentage Risk Increase over DPM	5%	For additional compounds emitted from vehicles (acetaldehyde, benzene, 1,3-butadiene, formaldehyde)	

NR = No Receptor for the category within 1000 m of the freeway.

Notes:

1. The I-15 MEIR is an assumed residential receptor at about 100 meters from the freeway because although there are no residential receptors near the segment modeled, there are a number of nearby residential receptors only 2 miles north of the modeled segment and traffic volumes are expected to be similar on I-15 where there are nearby residents.

Scenario 4: 2040 Plan Scenario 3 (2040PLSC3), Future Conditions under the Refined Regional Transportation Plan (RTP)
Diesel Exhaust HRA for SCAG 2016-2040 RTP/SCS

		Age	
		Fraction of Time at Home	Sensitivity Factors
Residential Breathing Rates are 95th Percentile			
Breathing Rate 3rd Trimester	361	L/kg-day	1 10
Breathing Rate 0 to <2 yrs	1090	L/kg-day	1 10
Breathing Rate 2 to <16 yrs	745	L/kg-day	1 3
Breathing Rate 16 to <70 yrs	290	L/kg-day	0.73 1
Breathing Rate 2 to <9 yrs	861	L/kg-day	1 3
Breathing Rate 16 to <30 yrs	335	L/kg-day	0.73 1
Off-site Worker Breathing Rates are 95th Percentile			
Breathing Rate 3rd Trimester	240	L/kg-day	10
8-hour Breathing Rate 16 to 70 years	230	L/kg-day	1
Day Care and School Breathing Rates are 95th Percentile			
8-hour Breathing Rate 0 to <2 years	1200	L/kg-day	10
8-hour Breathing Rate 2 to <9 years	640	L/kg-day	3
8-hour Breathing Rate 2 to <16 years	520	L/kg-day	3
DPM Cancer Potency	1.1	(mg/kg-day)^{-1}	
Percentage Risk Increase over DPM	5%	For additional compounds emitted from vehicles (acetaldehyde, benzene, 1,3-butadiene, formaldehyde)	

NR = No Receptor for the category within 1000 m of the freeway.

Notes:

1. The I-15 MEIR is an assumed residential receptor at about 100 meters from the freeway because although there are no residential receptors near the segment modeled, there are a number of nearby residential receptors only 2 miles north of the modeled segment and traffic volumes are expected to be similar on I-15 where there are nearby residents.

		Age	
		Fraction of Time at Home	Sensitivity Factors
Residential Breathing Rates are 95th Percentile			
Breathing Rate 3rd Trimester	361	L/kg-day	1 10
Breathing Rate 0 to <2 yrs	1090	L/kg-day	1 10
Breathing Rate 2 to <16 yrs	745	L/kg-day	1 3
Breathing Rate 16 to <70 yrs	290	L/kg-day	0.73 1
Breathing Rate 2 to <9 yrs	861	L/kg-day	1 3
Breathing Rate 16 to <30 yrs	335	L/kg-day	0.73 1
Off-site Worker Breathing Rates are 95th Percentile			
Breathing Rate 3rd Trimester	240	L/kg-day	10
8-hour Breathing Rate 16 to 70 years	230	L/kg-day	1
Day Care and School Breathing Rates are 95th Percentile			
8-hour Breathing Rate 0 to <2 years	1200	L/kg-day	10
8-hour Breathing Rate 2 to <9 years	640	L/kg-day	3
8-hour Breathing Rate 2 to <16 years	520	L/kg-day	3
DPM Cancer Potency	1.1	(mg/kg-day) ⁻¹	
Percentage Risk Increase over DPM	5%	For additional compounds emitted from vehicles (acetaldehyde, benzene, 1,3-butadiene, formaldehyde)	

NR = No Receptor for the category within 1000 m of the freeway.

Notes:

1. The I-15 MEIR is an assumed residential receptor at about 100 meters from the freeway because although there are no residential receptors near the segment modeled, there are a number of nearby residential receptors only 2 miles north of the modeled segment and traffic volumes are expected to be similar on I-15 where there are nearby residents.

APPENDIX E

Potential Cancer Risk Summary from MOVES2014

APPENDIX E: POTENTIAL CANCER RISK SUMMARY FROM MOVES2014

Kleinfelder was contracted by Sapphos Environmental, Inc. (Sapphos) through Southern California Association of Governments (SCAG) to prepare the health risk assessment (HRA) for sixteen freeway segments included in the 2016-2040 Regional Transportation Plan/ Sustainable Communities Strategy (RTP/STS) Program Environmental Impact Report (PEIR). Two models are typically used for highway emissions modeling: California Air Resources Board's (CARB's) EMFAC model and United States Environmental Protection Agency's (USEPA's) MOVES model. EMFAC2014 is used for calculating the diesel particulate matter (DPM) emission rates for the freeway traffic, and MOVES2014 is used to calculate the toxic emissions from the additional chemicals of concern. Due to time required to run the simulations required for this analysis and insignificant contributions to the overall risk from the additional chemicals of concern, the following methodology was adopted.

The MOVES2014 model calculates emissions from criteria and toxic pollutants from vehicles to be included as part of the HRA. Toxic air contaminants include the remaining four toxics for this analysis – acetaldehyde, benzene, 1,3-butadiene, and formaldehyde. These toxics account for only about 3.7% of the total risk while DPM makes up the remaining 96.3%, as determined by the HRA performed for the previous PEIR (Sierra Research, 2011). Risk from freeways is relatively large (100's to 1,000's of potential cancer risk per million exposed persons), therefore 3.7% is a relatively small percentage of the total pollutants contributing towards the risk. In addition, the MOVES2014 model is a very resource-intensive model that can take several to tens of hours per model run. For these reasons, Kleinfelder ran a sensitivity analysis involving running MOVES2014 for the cross-section of diesel vehicles traveling the freeway, calculated a potential cancer risk of each toxic pollutant to be analyzed, and demonstrated the similarities to data presented in the previous HRA (which was based on older USEPA emission models, specifically MOBILE6.2a).

The potential cancer risk from travel on the freeways is a function of traffic volume for each vehicle class (miles per year), emission factors per vehicle class (grams/mile), potential exposure of persons to the emissions (concentration and duration), and cancer slope factors (potency) of each chemical the person is exposed to. As discussed above, Sierra Research calculated that DPM was responsible for 96.3% of the total risk (from DPM, acetaldehyde, benzene, 1,3-butadiene, and formaldehyde) on a sample I-15 segment in the previous HRA. That calculation was based on EMFAC2007 and MOBILE6.2a emissions (predecessor models). EMFAC does not give individual toxic emission factors, thus the use of MOBILE6.2a and MOVES2014 is required to provide the toxics breakdown.

Kleinfelder confirmed that the output from MOVES2014 is consistent with the results found in the previous PEIR based on MOBILE6.2a. We did this by obtaining emission factors by vehicle class for DPM, acetaldehyde, benzene, 1,3-butadiene, and formaldehyde, and then calculating a "Potential Risk Factor" for each vehicle class and chemical. The "Potential Risk Factor" accounts for the different chemical potencies and emission factors of each chemical. The "Potential Risk Factor" calculated and shown in Attachment A is the emission factor (g/mile) times the cancer

slope factor (mg/kg-day)⁻¹). Basically, the Potential Risk Factor is a relative measure of risk, assuming that exposure and vehicle miles are constant.

The MOVES2014 data summaries in Attachment A show that DPM is responsible for 96.1% to 96.3% of the total risk for all vehicle classes, and nearly 99% of the total risk for heavy duty diesel fueled vehicles (combination long-haul vehicle class), which is the primary contributor to total cancer risk from all vehicles traveling on the freeway. These results are very consistent with the previous PEIR.

It is recognized that the vehicle miles are not constant for the individual vehicle classes. However, per the tables in Attachment A, the ratio of DPM risk to total risk does not vary much among vehicle classes. Likewise, the ratios of DPM and other toxics risk (acetaldehyde, benzene, 1,3-butadiene, and formaldehyde) to total risk by vehicle class will not change. Also, the relative risk from non-diesel vehicles is one to two orders of magnitude less than the relative risk from diesel-fueled vehicles. Accordingly, even if actual vehicle miles were considered for each vehicle class, the result that DPM is responsible for about 96% or more of the total risk would not change. (Note that the previous PEIR conclusion that DPM was responsible for 96.3% of the risk did account for the different miles traveled per vehicle class. Again, Kleinfelder's relative risk calculations with MOVES2014 are consistent with that result.)

Accordingly, Kleinfelder proceeded with basing the risk calculations on EMFAC2014 DPM (only) emission factors and then increase the DPM-only risk by 5% (conservative) to account for the additional toxic chemicals of acetaldehyde, benzene, 1, 3-butadiene, and formaldehyde, rather than running MOVES2014 for the toxics.

LIMITATIONS

This work was performed in a manner consistent with that level of care and skill ordinarily exercised by other members of Kleinfelder's profession practicing in the Southern California area, under similar conditions and at the date the services are provided. Our conclusions, opinions, and recommendations are based on a limited number of observations and data. It is possible that conditions could vary between or beyond the data evaluated. Kleinfelder makes no other representation, guarantee, or warranty, express or implied, regarding the services, communication (oral or written), report, opinion, or instrument of service provided.
